# A QUALITATIVE AND QUANTITATIVE SURVEY ON THE HELMINTH PARASITES OF FISHES FROM THE ASWAN HIGH DAM LAKE IN EGYPT* 

M.F.A. SAOUD**<br>Department of Zoology, Faculty of Science, Ain Shams University Faculty of Science, Al-Azhar University, Cairo, A. R. Egypt

#### Abstract

The present investigation is concerned with a helminthological survey of 19 species of fish collected along different seasons from the Aswan High Dam Lake in the southernmost part of Egypt. 615 out of 850 fish ( $72.4 \%$ ) are positive for helminth infections. The positive hosts are infected with one or more helminthic groups. The incidence of infections arranged in their order frequency is $26.6 \%$ for trematodes, $24.8 \%$ for acanthocephala, $22.6 \%$ for nematodes, $11.7 \%$ for cestodes and $0.1 \%$ for aspidocotyleans. The incidence of infection in male and female fish is almost nearly equal except in Lates niloticus where a certain species of nematodes is found in females but not in males. Digenetic trematodes, aspidocotyleans and acanthocephala are identified to the generic level and their incidence determined in various fish species. The incidence of single and simultaneous double infections with trematode genera are also determined to investigate the possible interactions between members of the parasitic fauna in their respective hosts. The incidence and intensity of fish infections with some trematodes and acanthocephala are studied throughout the range of their age to determine the effect of age on the characteristics of these infections.

## INTRODUCTION

It is widely accepted that qualitative and quantitative deficiencies of animal proteins could be corrected by an overall development of fish resources both in marine and other aquatic environments. The development of fish resources could be enhanced by the proper study of different aspects of fish biology, including fish parasitology (Williams, 1967).

In Egypt, particular attention is given to the development of fisheries to alleviate the pressing demands on animal proteins by the rapidly increasing population. Egyptian fisheries include mainly those of the Red Sea and the Mediterranean Sea territorial waters, the River Nile and the Aswan High Dam Lake in Upper Egypt. This lake, being one of the largest man-made lakes in Africa (coming only next to Lake Volta in Ghana) is selected as the site of the present investigation which is concerned with a general helminthological study of the parasitic fauna of fishes of the lake. At present, fish production from the lake forms a significant proportion of the Egyptian inland fisheries.

[^0]The characteristics of Lake Nasser and its fish fauna and productivity are outlined in a comprehensive review by Abdel-Latif (1974) which can be briefly summarised as follows:

The lake has been created by the construction of the Aswan High Dam in the southernmost part of Egypt and extends beyond the Second Cataract in the Sudan. It started in 1964 when storage began and reached a level of about 168 metres above sea level in 1971, the maximum level of storage being 183 metres above sea level. It lies in the subtropical region with hot summer climate and extends in a desert area with mountains and vast plains of varying heights being nearly restricted to the edge of the lake which therefore has a unique situation and is thus different from other African man-made lakes where plenty of vegetation is prevalent.

The length of the lake is about 480 kms (about 300 km for Lake Nasser in Arab Republic of Egypt and 180 km for Lake Nubia in the Sudan). The full reservoir is situated between the Aswan High Dam and the Second Cataract (Dal), between 23 ${ }^{\circ} 58^{\prime}$ - 20 $0^{\circ} 27^{\prime}$ north latitudes and $30^{\circ} 07^{\prime}-33^{0} 15^{\prime}$ east longitudes (Fig. 1).

The lake has characteristically numerous side branches, locally called 'Khors' which constitute about $75 \%$ of the total area of the reservoir. There are 85 important khors, 48 on the eastern side and 37 on the western side, which proved to be good fishing grounds. The total volume of the lake is about $157 \mathrm{Km}^{3}$ (Lake Nasser $130 \mathrm{Km}^{3}$ and Lake Nubia $27 \mathrm{Km}^{3}$ ). There is a seasonal fluctuation in the water level in the lake according to the amount of water gained and the discharge during different seasons.

The entire reservoir lies in an extremely arid environment. Occasional showers may happen in any period of the year, but there may be occasional heavy rains. The mean relative humidity recorded at Aswan is $13 \%$ in May-June and rises to $36 \%$ in December and falls off in the successive months. The mean monthly ambient temperature is around $34^{\circ} \mathrm{C}$ during June to August, but the lowest temperature of $15.8^{\circ} \mathrm{C}$ is recorded in January. The cool season lasts from December to February, the mean air temperature for this period is $16.5^{\circ} \mathrm{C}$. The hot weather prevails from April to October and the mean temperature for this period is $31.1^{\circ} \mathrm{C}$. The temperature rapidly rises in February-March and declines steadily during November.

The Zooplankton population of the lake is mainly represented by limnoplankton forms including Copepoda, Cladocera and Rotifera. In spite of the richness of the Zooplankton populations, their grazing effect on the Phytoplankton (mainly blue green algae) is negligible due to the dense growth of the latter.

The fish fauna of the lake is rich; Abdel-Latif (1974) recorded 57 species belonging to 15 families. The total fish landings of the lake increased from 750 tons in 1966 to 6716 tons in 1971.

## MATERIALS AND METHODS

The present investigation was carried out from 1974-1976, along different seasons, once every 3 months. Most fishes were caught by floating gill nets (Sakarota), trammel nets (Duk) and sunken-gill nets (Kobok) by special arrangement with Aswan Regional Planning Authority. On very few occasions certain species of fish were brought from the fish market platform at Aswan on the lake.

All fishes were examined as soon as possible after catching. Brief notes were made on the identification of host, its sex, age, measurements, weight, date of collection, locality, ... etc. The body surface, fins, gills, body cavity, gut, liver, heart, kidneys and eye-orbit were examined for helminth parasites; a hand lens or binocular dissecting microscope being used for the

Fig. 1. The Aswan High Dam Lake in Upper Egypt and Northern Sudan
examination. Collected material were washed, relaxed and fixed. Trematodes and cestodes were fixed in $70 \%$ alcohol and $5 \%$ formalin. Fixation of acanthocephala was done using Ristroph's fixative (Weesner, 1968). In the staining of trematodes, cestodes and acanthocephala, Alum carmine, Grenacher's alum carmine, Gower's carmine and acetocarmine were used.

## RESULTS AND DISCUSSION

## I. Incidence of Helminth Parasites

Altogether 850 fish belonging to 19 species, 14 genera and eleven families are examined for helminth parasites during the present investigation. Results are shown in Table (1) and can be summarized as follows:

1. General Incidence: 615 fish out of $850(72.4 \%)$ are positive for helminth infections. The positive hosts are infected with one or more groups of trematodes, cestodes, aspidocotyleans, nematodes and acanthocephala. Incidence of different groups arranged in their order of frequency is $26.6 \%$ for trematodes, $24.8 \%$ for acanthocephala, $22.6 \%$ for nematodes, $11.7 \%$ for cestodes and $0.1 \%$ for aspidocotyleans.
2. Trematode Infections: Digenetic trematodes have been reported in eight host species, belonging to five genera. These hosts are Barbus bynni, Bagrus bayad, B. docmac, Synodontis schall, S. serratus and Tetraodon fahaka. One type of metacercaria was found in Tilapia nilotica and T. galilaea. Amongst infected fish, the highest incidence of digenetic trematodes is recorded in Bagrus bayad (88.9\%) while the lowest is found in Tilapia nilotica (33.3\%).
3. Cestode infections: Cestodes are recorded from Barbus bynni, Clarias lazera and Malopterurus electricus. The highest incidence is found in Malopterurus electricus (96\%) while the lowest is found in Clarias lazera (5\%).
4. Aspidocotylean infections: These parasites are very rarely seen, being only recorded in one Synodontis schall, with an incidence of $0.1 \%$.
5. Nematode infections: These are recorded from eight species belonging to five genera. The positive hosts include: Labeo horie, L. coubie, Synodontis schall and S. serratus, Lates niloticus, Tilapia nilotica and T. galileae and Hydrocyon forskalii. The highest incidence of nematodes is found in Labeo horie ( $75.0 \%$ ) and the lowest in Lates niloticus (10.0\%).
6. Acanthocephala infections: These helminth parasites are reported from seven species of fish, belonging to five genera. The fish hosts are: Clarias lazera, Bagrus bayad, B. docmac, Lates niloticus, Tilapia galilaea, T. nilotica and Tetraodon fahaka. The highest incidence of acanthocephala is found in Tilapia nilotica ( $96.7 \%$ ) and the lowest in Clarias lazera $(10.0 \%)$.

## II. INCIDENCE OF HELMINTH PARASITES IN MALE AND FEMALE FISH

The data presented in Table (1) has been subjected to close analysis in order to determine the difference between the incidence of helminths in male and female fish. The results obtained are given in Table (2) and summarized as follows:

The total incidence of infection in male and female fish is almost nearly equal being $96.1 \%$ and $89.2 \%$ respectively. There are no significant differences in the incidence of different helminth groups in both sexes of fish, the only exception to that rule is Lates niloticus where certain nematodes are found in females but not males. In this case, a certain species of nematodes is found in the ovaries of the fish but never in the testes.

Table (1)
Incidence of Trematodes, Cestodes, Aspidocotylea, Nematodes and Acanthocephala in Fishes.

## III. Incidence of Digenetic Trematode and Aspidocotylean Genera in Infected Fish

The digenetic trematodes and aspidocotyleans collected from different hosts during the present study have been identified to the generic level, and the incidence of the various genera are shown in Table (3) and summarized as follows:

## A. Digenetic Trematode Infections

1. Astiotrema Infections: This genus is recorded only from Tetraodon fahaka: without a single exception all helminthologically positive fish are infected with this genus of trematodes.
2. Acanthostomum Infections: This genus is recorded only from genus Bagrus. Its incidence in two infected Bagrus species, varies from 76.9\% in Bagrus docmac to $87.5 \%$ in Bagrus bayad.
3. Allocreadium Infections: This genus is recorded only from Barbus bynni, its incidence reaching $58.2 \%$.
4. Haplorchoides Infections: This genus is only found in the genus Bagrus. Without a single exception all infected fish of either B. bayad or B. docmac have this trematode genus.
5. Basidiodiscus Infections: This genus is only found in the genus Synodontis. Its incidence is high, varying from $96.4 \%$ in $S$. schall to $100 \%$ in $S$. serratus.
6. Sandonia Infections: This genus is only found in the genus Synodontis, with an incidence of $96.4 \%$ in S. schall and $100 \%$ in S. serratus.
7. Clinostomum (metacercaria) Infections: This metacercarial stage of the genus Clinostomum is only found in fishes of the genus Tilapia. All infected fish have this metacercarial stage.

## B. Aspidocotylean Infections

Aspidogaster Infections:
An infection with this genus has been found only in one Synodontis schall out of 50 specimens examined.

## IV. The Incidence of Acanthocephalan Genera in Infected Fishes

The acanthocephala collected from different hosts during the present study have been identified to the generic level, and the incidence of the various genera are shown in Table (4) and summarized as follows:

## 1. Acanthosentes Infections

This genus is only recorded from the genus Tilapia; all infected T. nilotica and T. galilaea have this genus of acanthocephala. The intensity of infection was at its maximum in summer and reached a minimum in winter. The number of parasites per fish ranged from 8-23 in summer, while the corresponding figure for winter was 3-7.

## 2. Paragorgorhynchus Infections

This genus is recorded from five species belonging to four genera including Lates niloticus, Bagrus docmac, B. bayad, Tetraodon fahaka and Clarias lazera. The highest incidence amongst infected fish is $95 \%$ in Lates niloticus while the lowest one is $11.1 \%$ in Bagrus bayad, $13.3 \%$ in
B. docmac and $12.8 \%$ in Tetraodon fahaka. The intensity of infection also varied in different genera of fishes, being 87-200 per fish in Lates niloticus, 9-22 in Tetraodon fahaka, 4-15 in Bagrus bayad and B. docmac and 4-7 in Clarias lazera.

The worms collected from Lates niloticus are larger than those from other hosts, also the number of eggs in female worms, used as indication of fertility, is highest in Lates niloticus in comparison with other hosts. This would indicate that Lates niloticus is a more favourable host of the genus Paragorgorhynchus than the other hosts.

Table (4)
Incidence of Acanthocephalan Genera in Infected Fish

| Fish | Total No. <br> Infected |  | Genera |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Acanthosentes | Paragorgorhynchus |  |  |
| Clarias lazera |  | 0 | 0 | No. | $\%$ |  |
| Bagrus bayad | 45 | 0 | 0 | 2 | 66.7 |  |
| Bagrus docmac | 15 | 0 | 0 | 5 | 11.1 |  |
| Lates niloticus | 100 | 0 | 0 | 95 | 13.3 |  |
| Tetraodon fahaka | 70 | 0 | 0 | 95.0 |  |  |
| Tilapia nilotica | 58 | 58 | 100.0 | 0 | 12.9 |  |
| Tilapia galilaea | 40 | 40 | 100.0 | 0 | 0 |  |
| Total | 331 | 98 | 29.6 | 113 | 34.1 |  |

## V. Single (Pure) and Simultaneous Double Infections With Two Trematode Genera

Our previous studies on digenetic trematodes of bats in Egypt indicated that there were some interactions between members of the parasitic fauna in these hosts. Infections with certain trematode genera were found to be antagonistic to infections with other genera. On the contrary, certain trematode genera occurred only in the presence of some other genera of parasites (Saoud and Ramadan, 1976).

This phenomenon is studied in digenetic trematodes of freshwater fishes. The incidence of single and simultaneous double infections with trematode genera in different species of fish are determined and the results obtained are given in Tables (5) ạd (6). These results can be summarized as follows:

## A. Single (Pure) Infections With One Genus of Trematodes:

The total incidence of pure infections with one genus of trematodes is almost twice that of double infections with two genera of trematodes, being $65.5 \%$ and $34.5 \%$, respectively.

The lowest incidence with one genus of trematodes is recorded from Bagrus bayad (12.5\%) and B. docmac ( $23.0 \%$ ) while the other species of fish show an incidence of $100.0 \%$ in all cases.

Table (5)
Incidence of Single and Double Infections With Trematode Genera in Fishes

| Fish | Total Number Infected | Infections |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | One Genus |  | Two Genera |  |
|  |  | No. | \% | No. | \% |
| Barbus bynni | 32 | 32 | 100.0 | 0 | 0 |
| Bagrus bayad | 40 | 5 | 12.5 | 35 | 87.5 |
| Bagrus docmac | 13 | 3 | 23.0 | 10 | 76.9 |
| Synodontis schall | 27 | 0 | 0 | 27 | 100.0 |
| Synodontis serratus | 6 | 0 | 0 | 6 | 100.0 |
| Tilapia nilotica* | 20 | 20 | 100.0 | 0 | 0 |
| Tilapia galilaea* | 25 | 25 | 100.0 | 0 | 0 |
| Tetraodon fahaka | 63 | 63 | 100.0 | 0 | 0 |
| Total | 226 | 148 | 65.5 | 78 | 34.5 |

${ }^{*}$ Metacercaria
Pure infections with one trematode genus, recorded from five genera of fishes with eight species, are as follows:

1. Genus Astiotrema: The incidence of this genus in pure infections is very high ( $100 \%$ ) in Tetraodon fahaka.
2. Genus Haplorchoides: The incidence of pure infections in this genus is low (12.5\%) in Bagrus bayad and (23\%) in Bagrus docmac.
3. Genus Allocreadium: The incidence of this genus in pure infections is $100 \%$ in Barbus bynni.
4. Genus Clinostomum (metacercaria): The metacercarial stage of genus Clinostomum is recorded in $100 \%$ of infected Tilapia nilotica and T. galilaea.

## B. Simultaneors Infections With Two Genera of Trematodes

Simultaneous infections of some fishes with two genera of trematodes have been encountered in the present study.

The total incidence of two infection with trematode genera is $34.5 \%$. These infections are recorded from two genera of fishes with four species. The following combinations of trematode genera have been found in such infections:

1. Acanthostomum + Haplorchoides:

The incidence of this combination is $76.9 \%$ in Bagrus docmac and $87.5 \%$ in Bagrus bayad. This

Table（0）
Incidence of Various Combinations of Trematode Genera in Fishes

| Trematode genera | Infected fish |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

|  | No． | \％ | No． | \％ | No． | \％ | No． | \％ | No． | \％ | No． | \％ | No． | \％ | No． | \％ |
| Astiotrema only | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 63 | 100.0 |
| Acanthostomum only | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Haplorchoides only | 0 | 0 | 5 | 12.5 | 3 | 23.0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Acanthostomum + Haplorchoides | 0 | 0 | 35 | 87.5 | 10 | 76.9 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Allocreadium only | 32 | 100.0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Clinostomum <br> （Metacercaria） | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 20 | 100.0 | 25 | 100.0 | 0 | 0 |
| Basidiodiscus only | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Sandonia only | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Basidiodiscus＋ Sandonia | 0 | 0 | 0 | 0 | 0 | 0 | 27 | 100.0 | 6 | 100.0 | 0 | 0 | 0 | 0 | 0 | 0 |

combination is more commonly seen in young fishes than in the older ones.

## 2. Basidiodiscus + Sandonia:

This combination is recorded from all infections of Synodontis schall and S. serratus. In no single case either parasites is found alone in the infected host.

## VI. Dispersion of Parasites With the Age of Host

Changes in the parasite fauna of a host with age have been studied by some workers, the length and weight of fish being used as indication of age (Elton, Ford and Baker 1931, Gorbunova 1936, Ackert, Edgar and Frick 1939, Frick and Ackert 1948, Sinha and Srivastava 1958, and Gray 1972.)

Dogiel (1961) suggested that in the majority of cases both the numbers and diversity of parasites increased with the age of the fish, especially those parasites with a direct life cycle. A similar situation is found within bird populations. Gray (1972) and Croll (1973) reported that, the parasite populations in birds depend on age and sex of their hosts.

Kennedy, (1975) reported that the incidence and the level of infection of many species of parasites increased with the age of the host. Change in age, however, often also means a change in structure, behaviour or diet of host, and so also a change in the probability of infection. That changes in host structure are responsible for changes in the infection are shown in the protozoon Myxosoma cerebralis. This species is only able to infect cartilage, and so its incidence declines in older rainbow trout fishes as ossification progresses. Similarly, the incidence of parasites that live in the Bursa fabricii of birds also decline with age of host. In contrast, Trypanosoma equiperdum is transmitted during coitus, and so only occurs in mature animals.

In the present investigation, some parasites showed a significant dispersion relation throughout the age of their hosts, including the incidence and intensity of infection. These results can be summarized as follows:

1. The incidence and intensity of infection with the acanthocephalan genus Paragorgorhynchus Golvan, 1957 in Lates niloticus increase with the age of fish.
2. Also, the incidence and intensity of infection with the acanthocephalan Acanthosentis Verma and Datta (1929) in Tilapia nilotica and T. galilaea increase with age of the fish.
3. The incidence and intensity of infection with trematodes of sub-genus Acanthostomum (Atrophocaecum) Bhalerao, 1940 in Bagrus bayad and B. docmac decrease with the age of fish.
4. The incidence of genus Haplorchoides Chen, 1949, is almost constant throughout the age of fishes of genus Bagrus, but the intensity of infection decreases with the increase of age. The same result is obtained with trematodes of genus Astiotrema Looss, 1900 from Tetraodon fahaka.
5. The infection of fishes: Bagrus bayad, B. docmac, Tetraodon fahaka and Clarias lazera with acanthocephala of the genus Paragorgorhynchus Golvan, 1957 is only recorded from older fish, no young fish are infected.
6. The incidence and intensity of infection with nematodes increase with age in Hydrocyon forskalii.

## ACKNOWLEDGEMENT

The writers are deeply grateful to Dr. A.F. Abdel-Latif, Vice President of the Egyptian Academy of Scientific Research and Technology and former Director of Lake Nasser Development Centre for his support and unfailing help during the present work.
